

## Linux Cheatsheet for Splunk Classes

Command	Description	Example
<b>cd</b> <i>dir</i>	Change directory to <i>dir</i> (As in Windows, .. is the parent directory and . is the current directory)	cd /opt cd /opt/splunk/bin
<b>cd</b> ~	Change directory to your home directory	cd ~
<b>chmod</b> <i>p fname</i>	Changes the permissions of the file <i>fname</i> based on <i>p</i> (see <b>man</b> command for more info) The example adds execute permissions to a file	chmod +x myScript.sh
<b>cp</b> <i>fname newname</i>	copy the file <i>fname</i> to <i>newname</i> ; <i>newname</i> can include a directory path	cp 1.txt 2.txt
<b>echo</b> <i>msg</i>	Display the <i>msg</i> (after command line variable substitution and file name expansion)	echo \$PATH
<b>find</b> . -name " <i>name</i> "	Look for the file <i>name</i> , starting in the current directory. The example uses a wildcard.	find . -name "input*"
<b>ls</b> <i>dirname</i>	List the files in the named directory; if no directory is named, list the files in the current directory	ls splunk/etc/users
<b>ls</b> -l	Display a "long" (detailed) list of the files	ls -l
<b>man</b> <i>cmd</i>	Provides help for the command <i>cmd</i>	man cd
<b>mkdir</b> <i>dirname</i>	Creates a new directory named <i>dirname</i>	mkdir change
<b>more</b> <i>fname</i>	Displays the contents of <i>fname</i> , a page at a time. Hit space to move to the next page and <b>q</b> to quit.	ps -ef   more more myFile.txt
<b>mv</b> <i>fname newname</i>	rename or move the file <i>fname</i> to <i>newname</i> ; <i>newname</i> can specify a new file name (rename) or a directory name (move) or both The example moves a file into a subdirectory	mv 1.txt ~/myDir
<b>nano</b> <i>fname</i> <b>ctrl-X</b>	Starts the nano editor, editing <i>fname</i> Use <b>ctrl-X</b> to save your edits	nano inputs.conf
<b>ps</b> -ef	ps displays the status of running processes; the -ef provides a full listing for every process	ps -ef
<b>pwd</b>	Displays the name of the current directory	pwd
<b>rm</b> <i>fname</i>	delete (remove) the file <i>fname</i>	rm 1.txt
<b>rmdir</b> <i>dirname</i>	removes the empty directory <i>dirname</i>	rmdir myDir
<b>source</b> <i>fname</i>	Executes the script <i>fname</i> within the current process; can be used to reload the .bashrc profile	source ~/.bashrc
<b>su</b> - <i>username</i>	Switch to the user account named <i>username</i> If you are not logged in as root, you will be prompted for the password.	su - user3
<b>sudo</b> <i>command</i>	Execute the <i>command</i> as root. Your account must have special privileges for this to work, otherwise you must provide the root password. <b>sudo su</b> is used to switch to the root login, but this is generally regarded as an unsafe practice in production.	sudo rm /tmp/x.txt
<b>touch</b> <i>fname</i>	If the file exists, update its modification time. If the file does not exist, create an empty file called <i>fname</i> .	touch 1.txt
<b>wget</b> <i>args</i>	Downloads a file from a web site. The args can usually be cut-and-pasted from the <b>wget</b> command example on the web site that is supplying the file.	See download page at splunk.com

### Running Scripts or Programs

To run a program or script, simply type its name (including the extension, if any). Depending on how you have set the \$PATH variable, you may need to include the path. For example, to execute myScript – a shell script that is located in the current directory:

**./myScript.sh**
